

# Long Term Planning of Leakage Reduction

Stephen Tooms – Hyder Consulting  
Presented by Stuart Trow - Consultant  
June 2010

- Problems with leakage modelling
- The approach taken
- The two modelling techniques used
- The yield curves from leakage reduction options
- Case Study results
- Uncertainty and sensitivity
- Conclusions

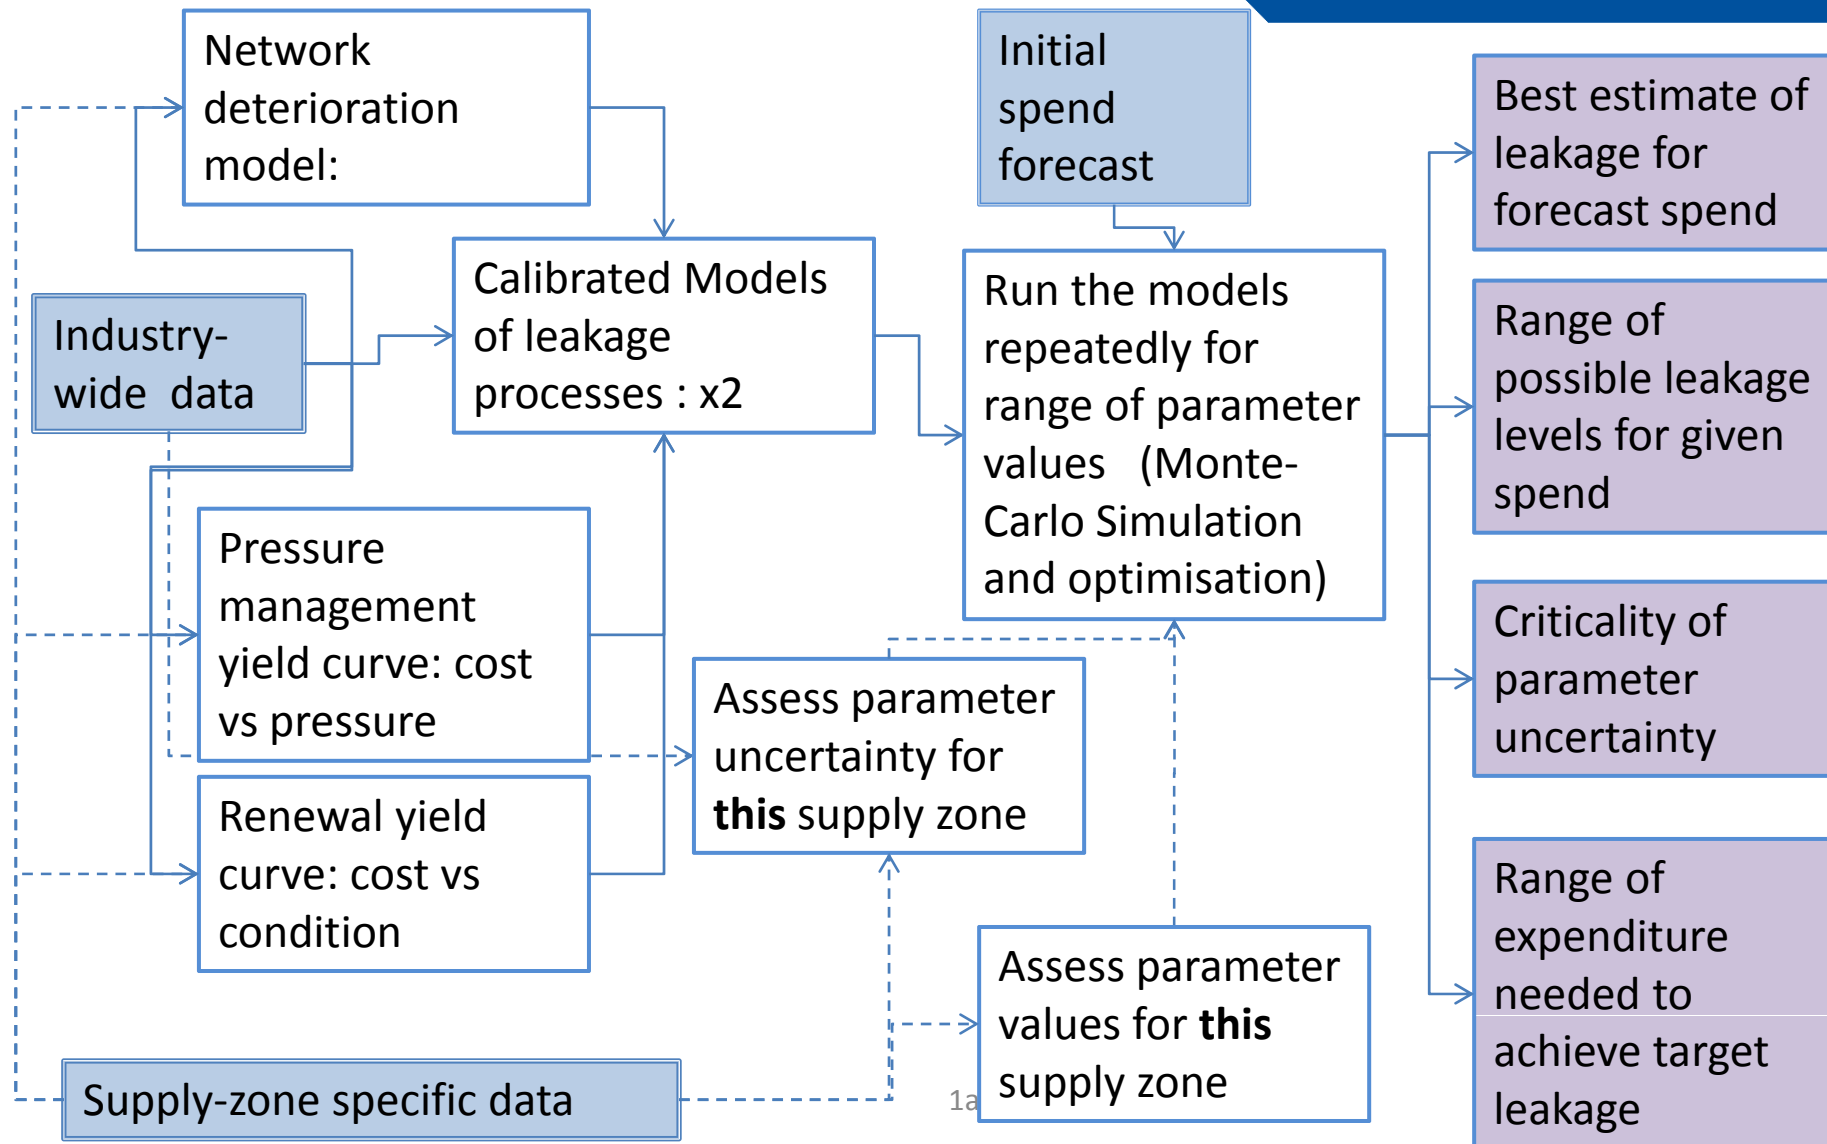

## **Mature water supply networks**

- Water resource planning timescales in decades
- Network renewal at similar timescales and high capital cost
- Uncertainty in long term effects of alternative, lower cost, approaches
- Uncertainty in the leakage reduction that can be achieved leads to a risk of failure of water resource plans.

## **Leakage reduction concessions**

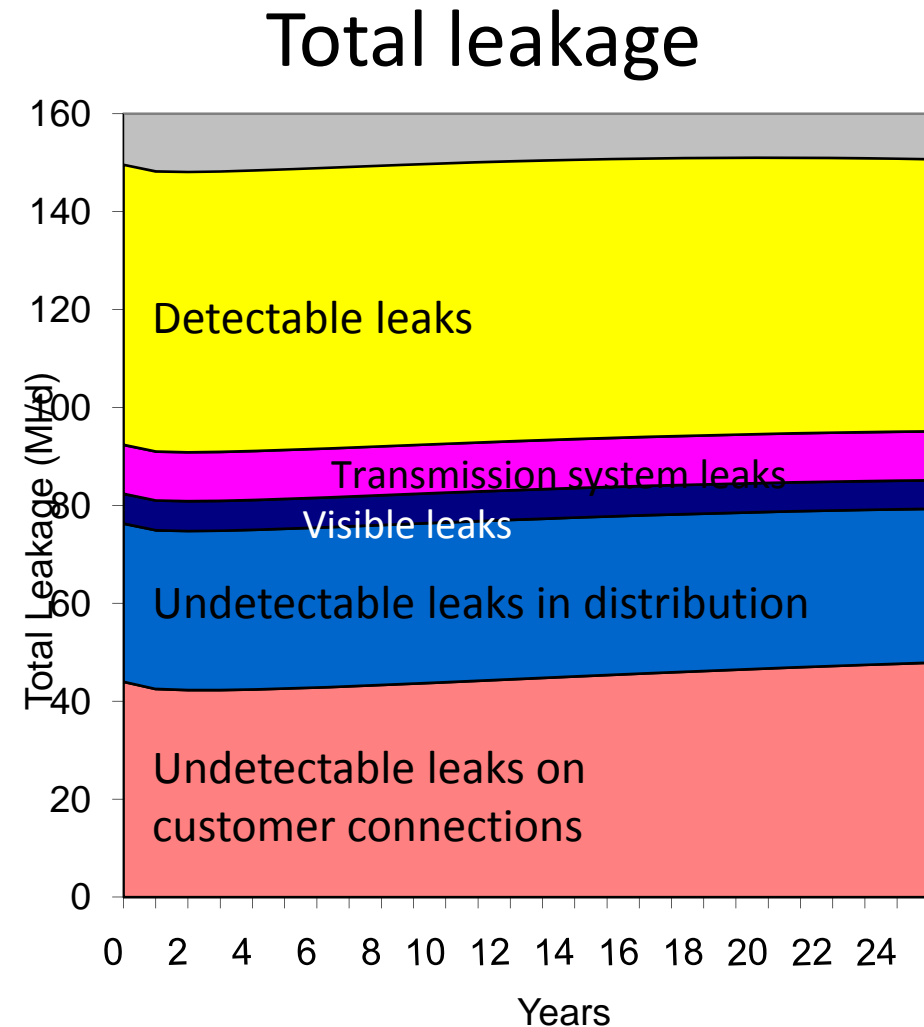

- Minimal initial information on network performance
- Long term agreements
- Targets agreed at an early stage
- A need by all parties to understand the costs and risks

# Our approach

## Model 1- Components

- BABE-type model
- Leaks occur and persist at full flow rate
- Leakage from detectable leaks dependent on detection expenditure
- All components are pressure dependent

## Model 2 – Leak growth

- Individual leaks grow
- Growth rate dependent on pressure
- Number of leaks dependent on network condition
- Leaks become detectable at threshold flow rate
- Probability of detection dependent on detection expenditure

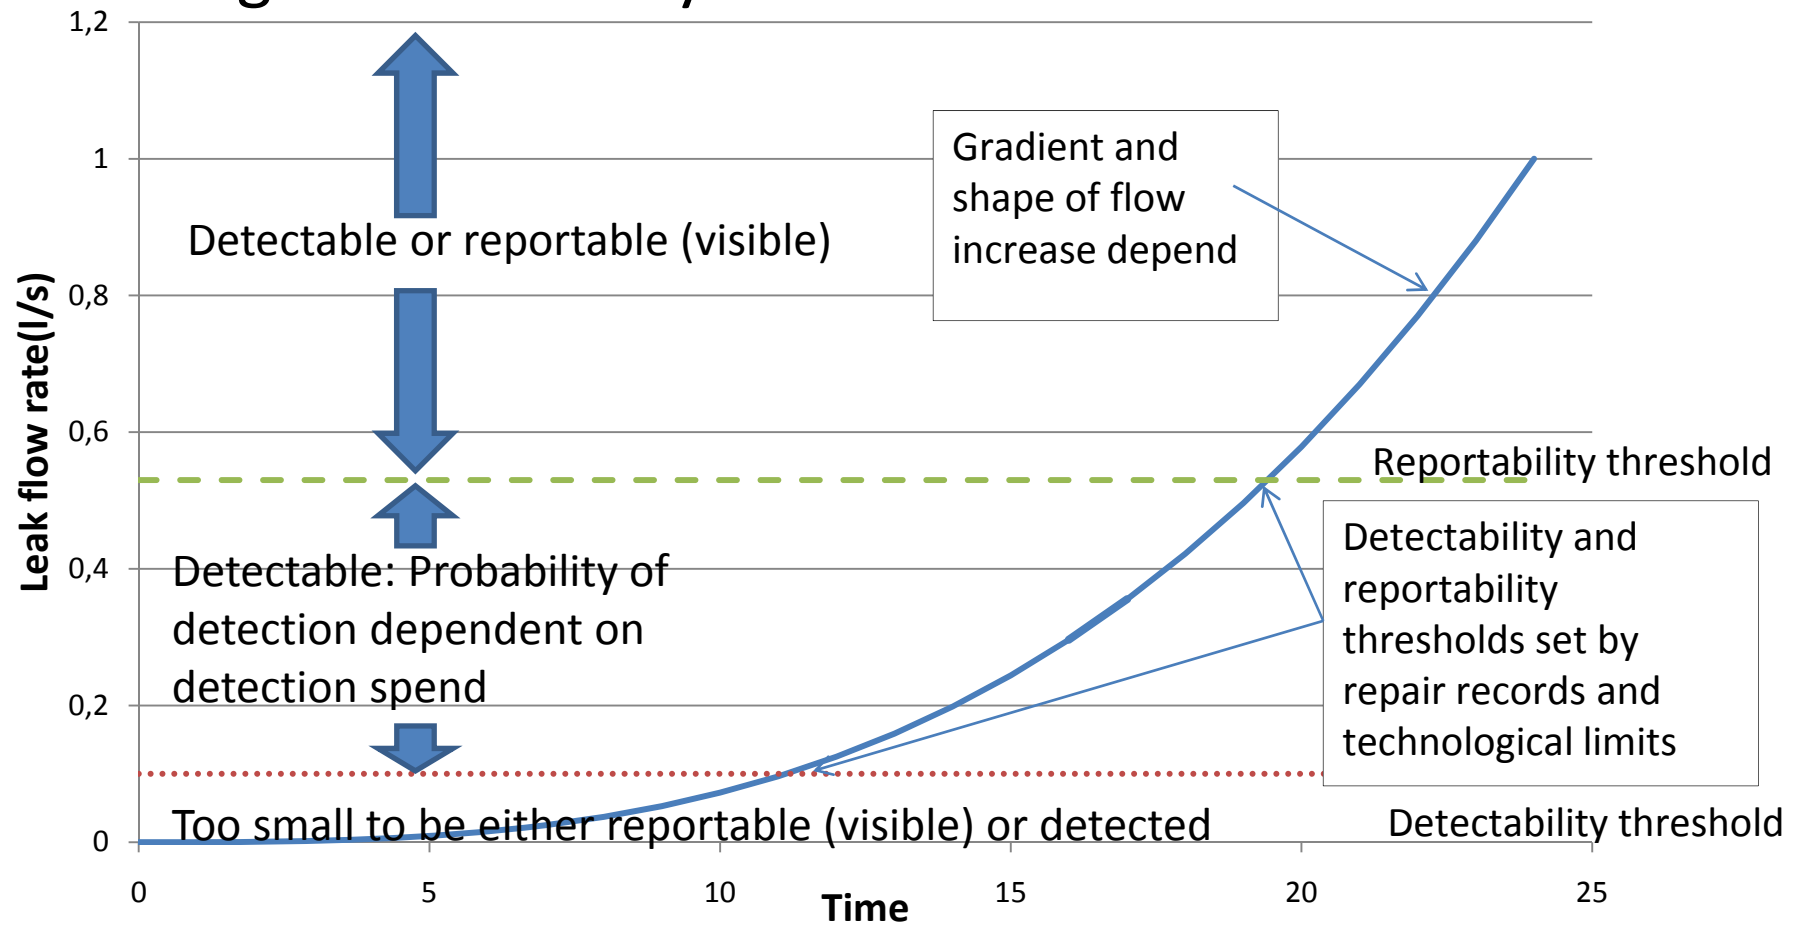

## Total leakage

# Leakage models – model 2

## Leak growth: History of an individual leak

# Comparison of Techniques

Model	Leak occurrence	Detection productivity	Pressure relationships	Impact of renewal
1-Component approach	Separate mains, connection leaks. Leaks occur at full flow rate	Inverse leak-duration vs ALC spend relationship	Leak flow rates $\propto P$ Breakout rate $\propto P^{N3}$	Reduces breakout rate and background leakage
2-Leak growth approach	Leak growth with shape factor	Probabilistic dependent on flow rate	Growth rate $\propto P$ Breakout rate $\propto P^{N3}$	Reduces breakout rate and background leakage

# Yield assumptions-detection

- Model 1:  $\frac{dL}{dt} = NRR - c.S.Lv$

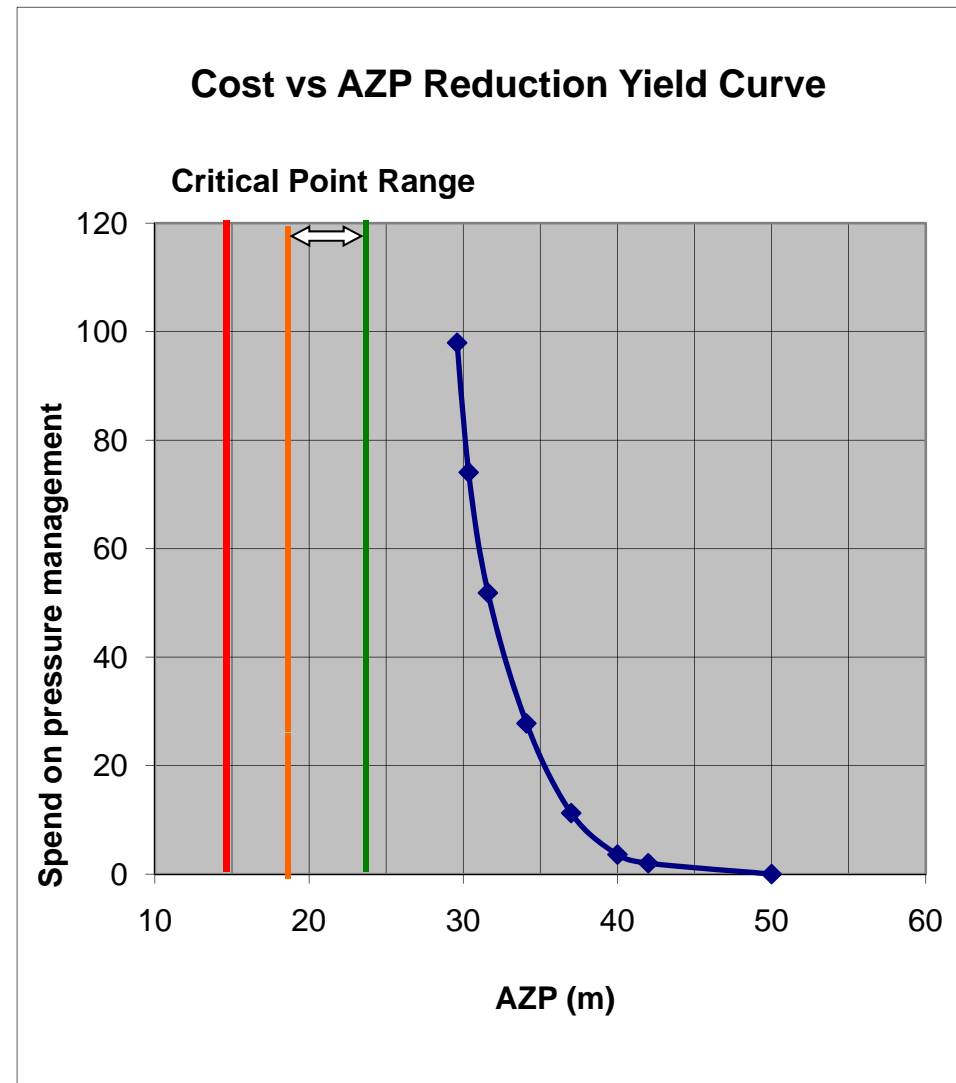

# Pressure management yield curve

- Seven stages:

- 1.“Natural” AZP- 50m
- 2.Current AZP -42m
- 3.Flow modulation on existing- 40m
- 4.Further reduction on existing zones -37m
- 5.PRVs on all existing DMAs- 34m
- 6.Splitting DMAs(x2) - 31m
- 7.Individual properties- 30m

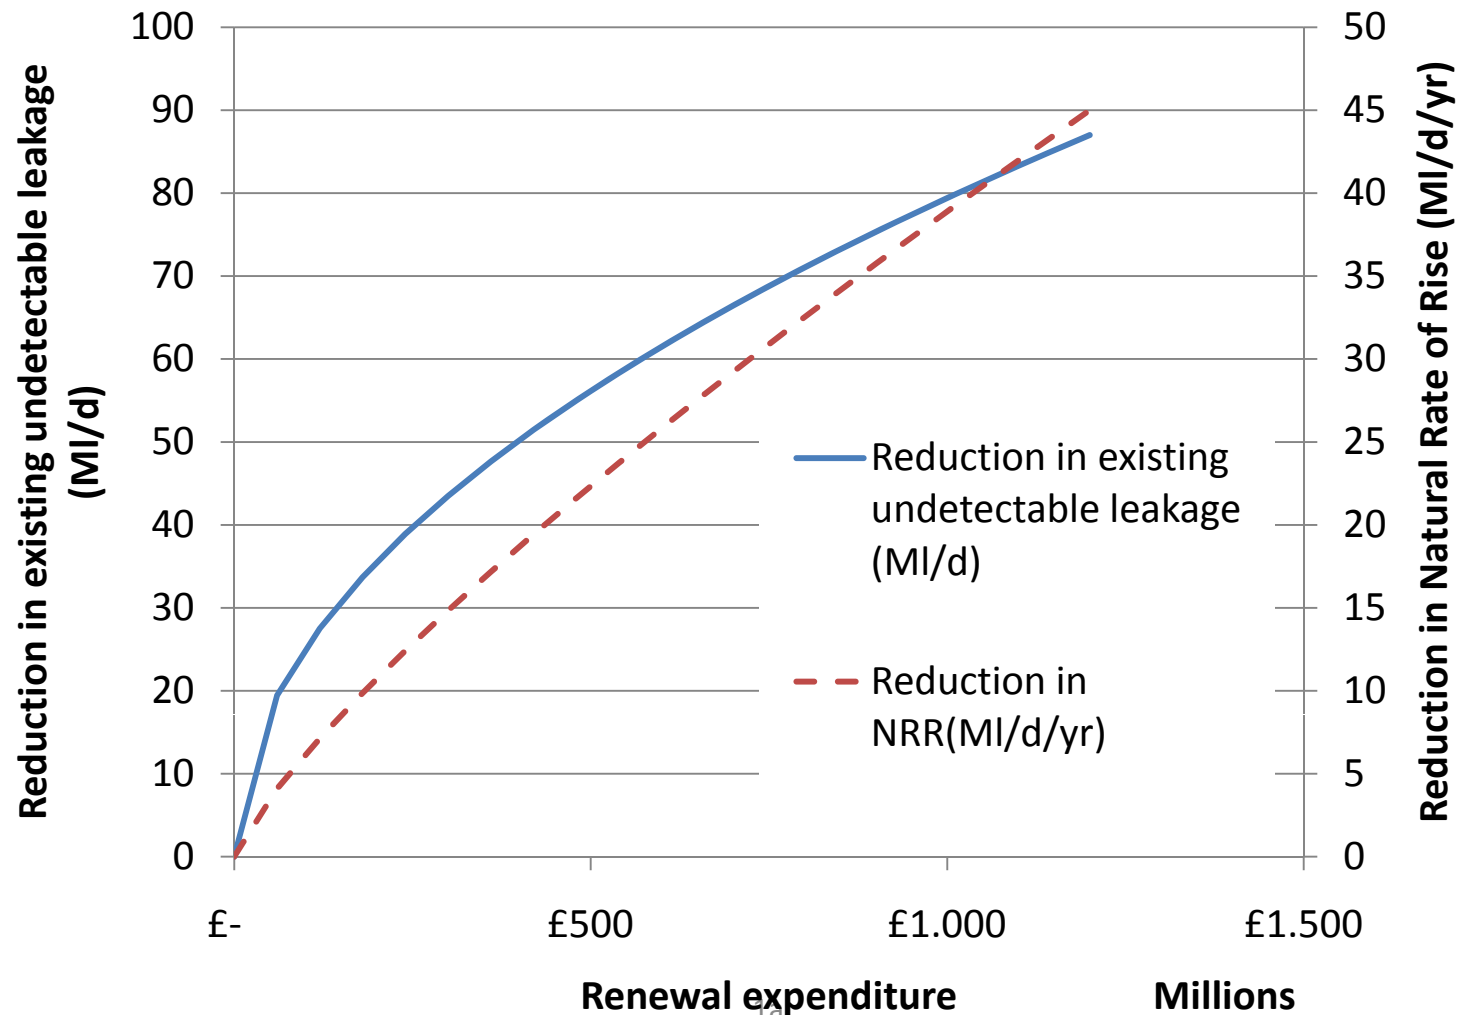

# Leakage model-renewal

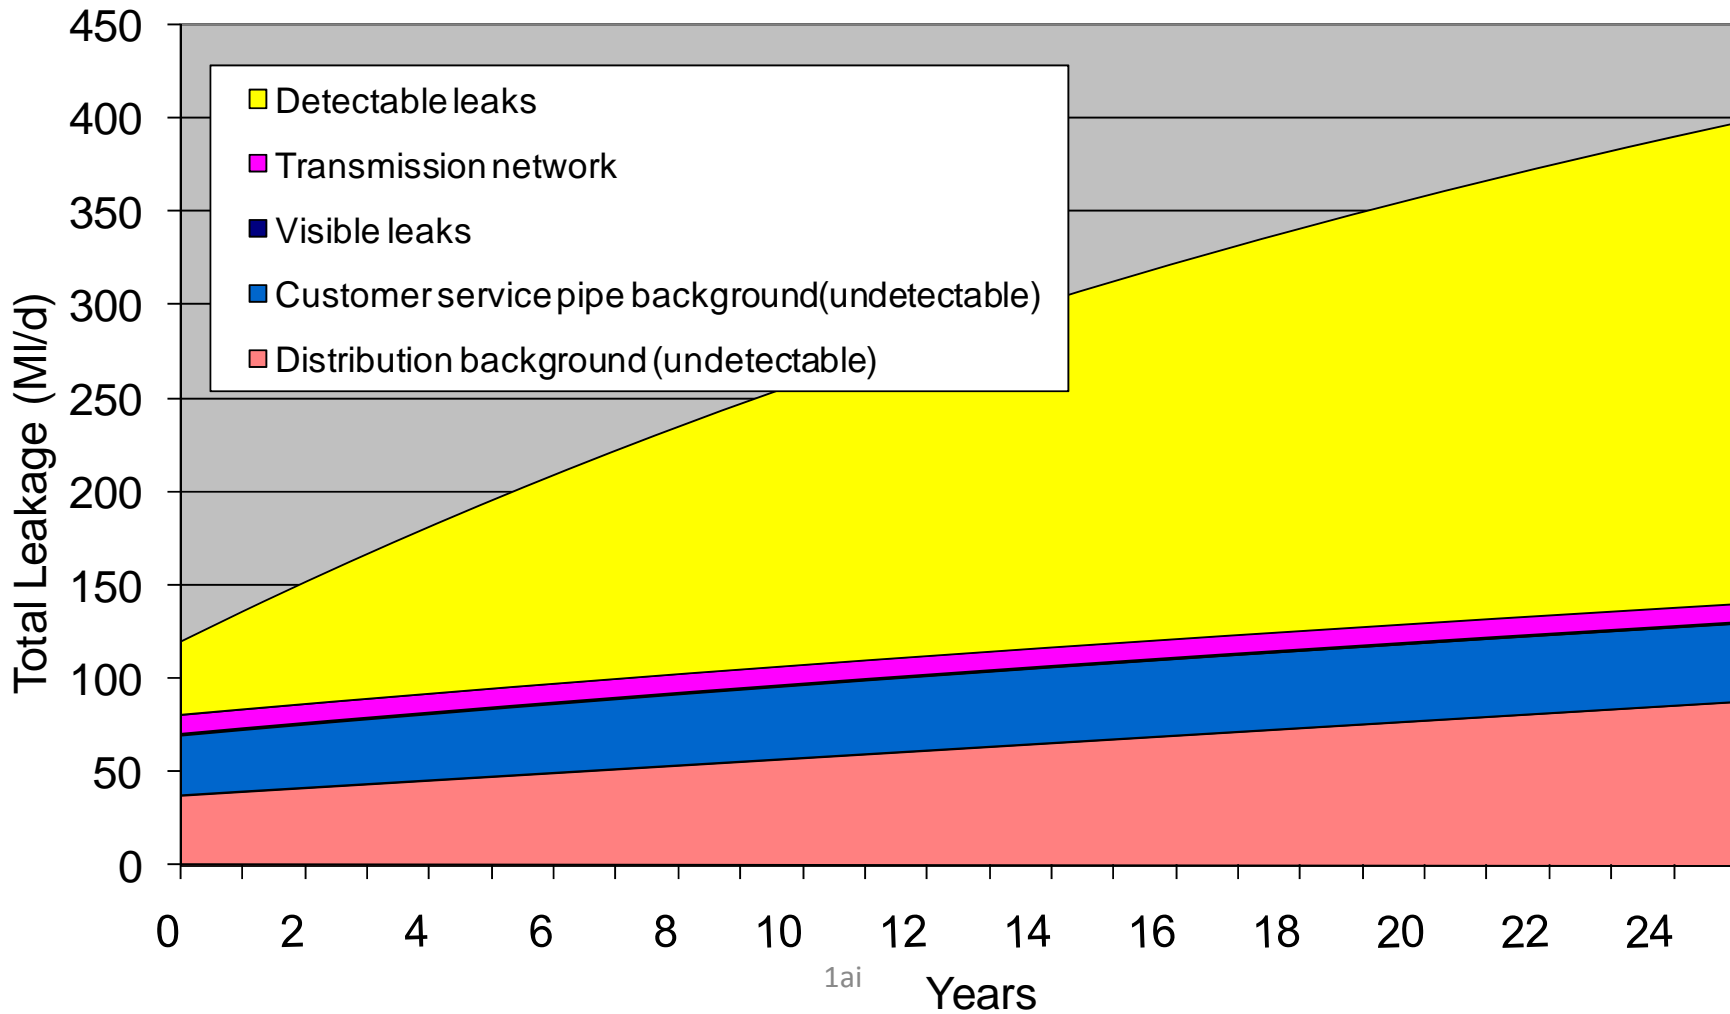

- Pareto curve giving distribution of background
- Pareto curve giving distribution of NRR
- Select worst first (in background or NRR)
- Apply new background and NRR to renewed network using research results
- Background deteriorates with time
- Selection by NRR or background makes little difference
- Assuming no correlation between background and NRR (conservative assumption)

# Yield curve: renewal

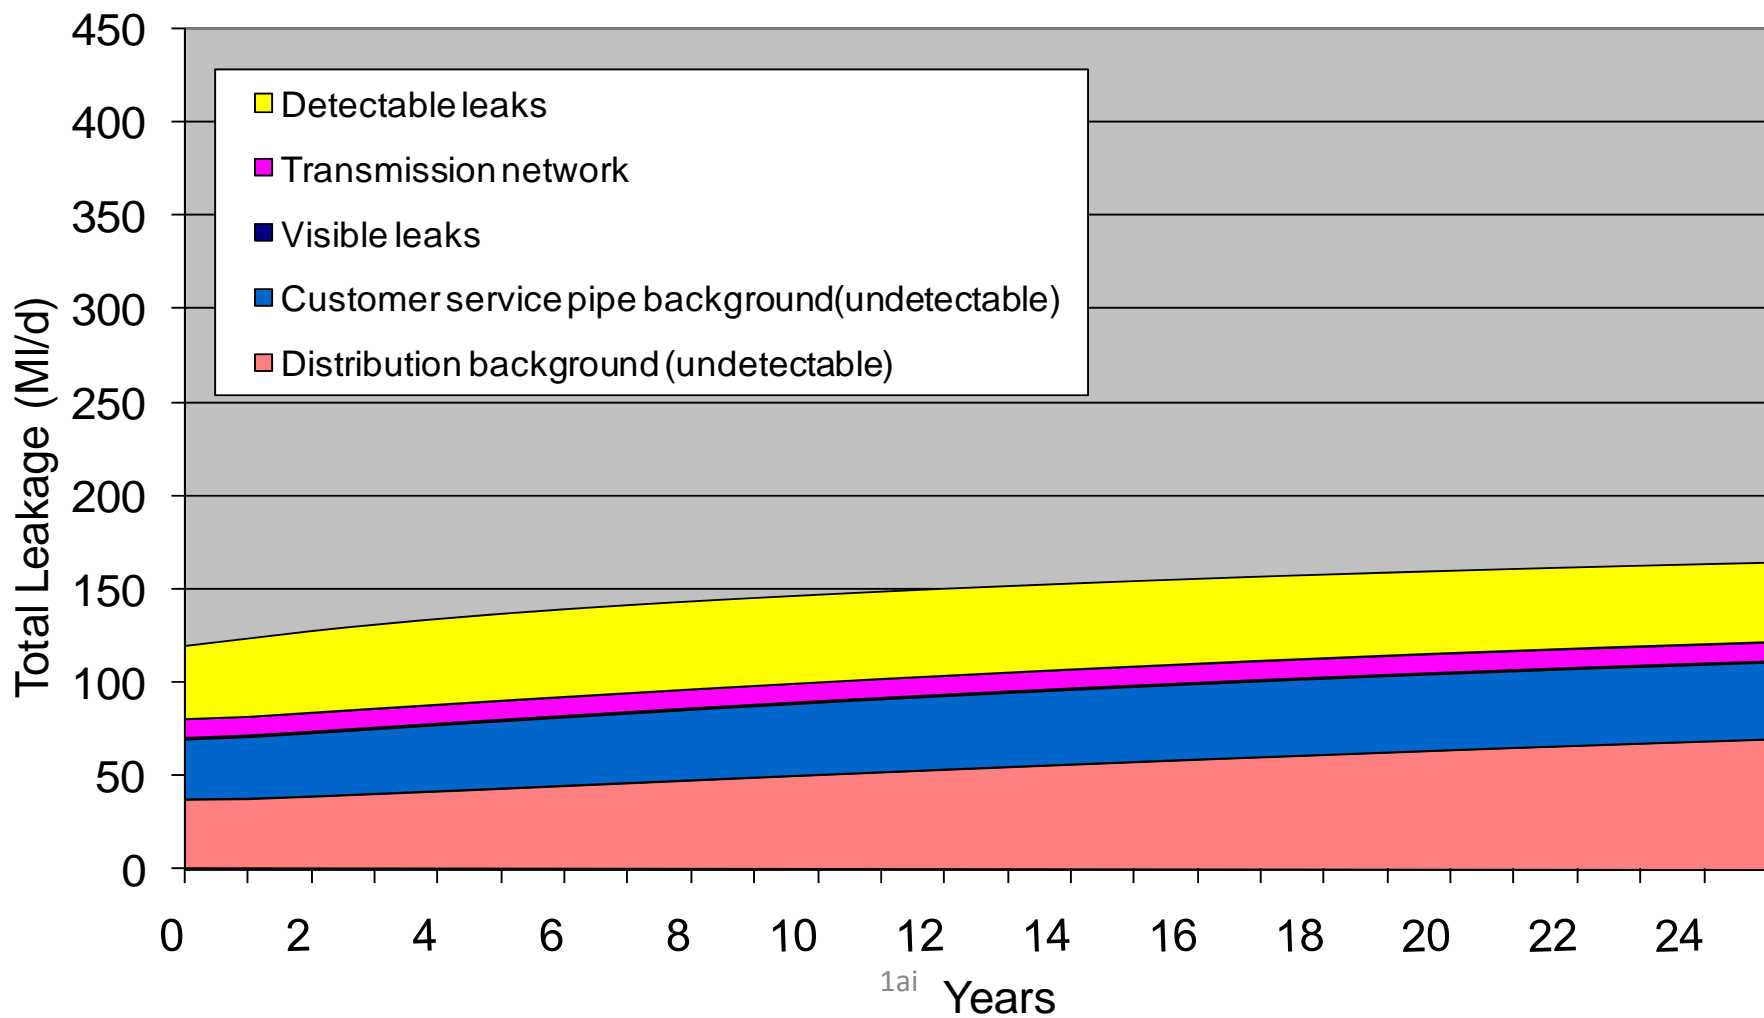

# Outputs for an example company: do-nothing baseline

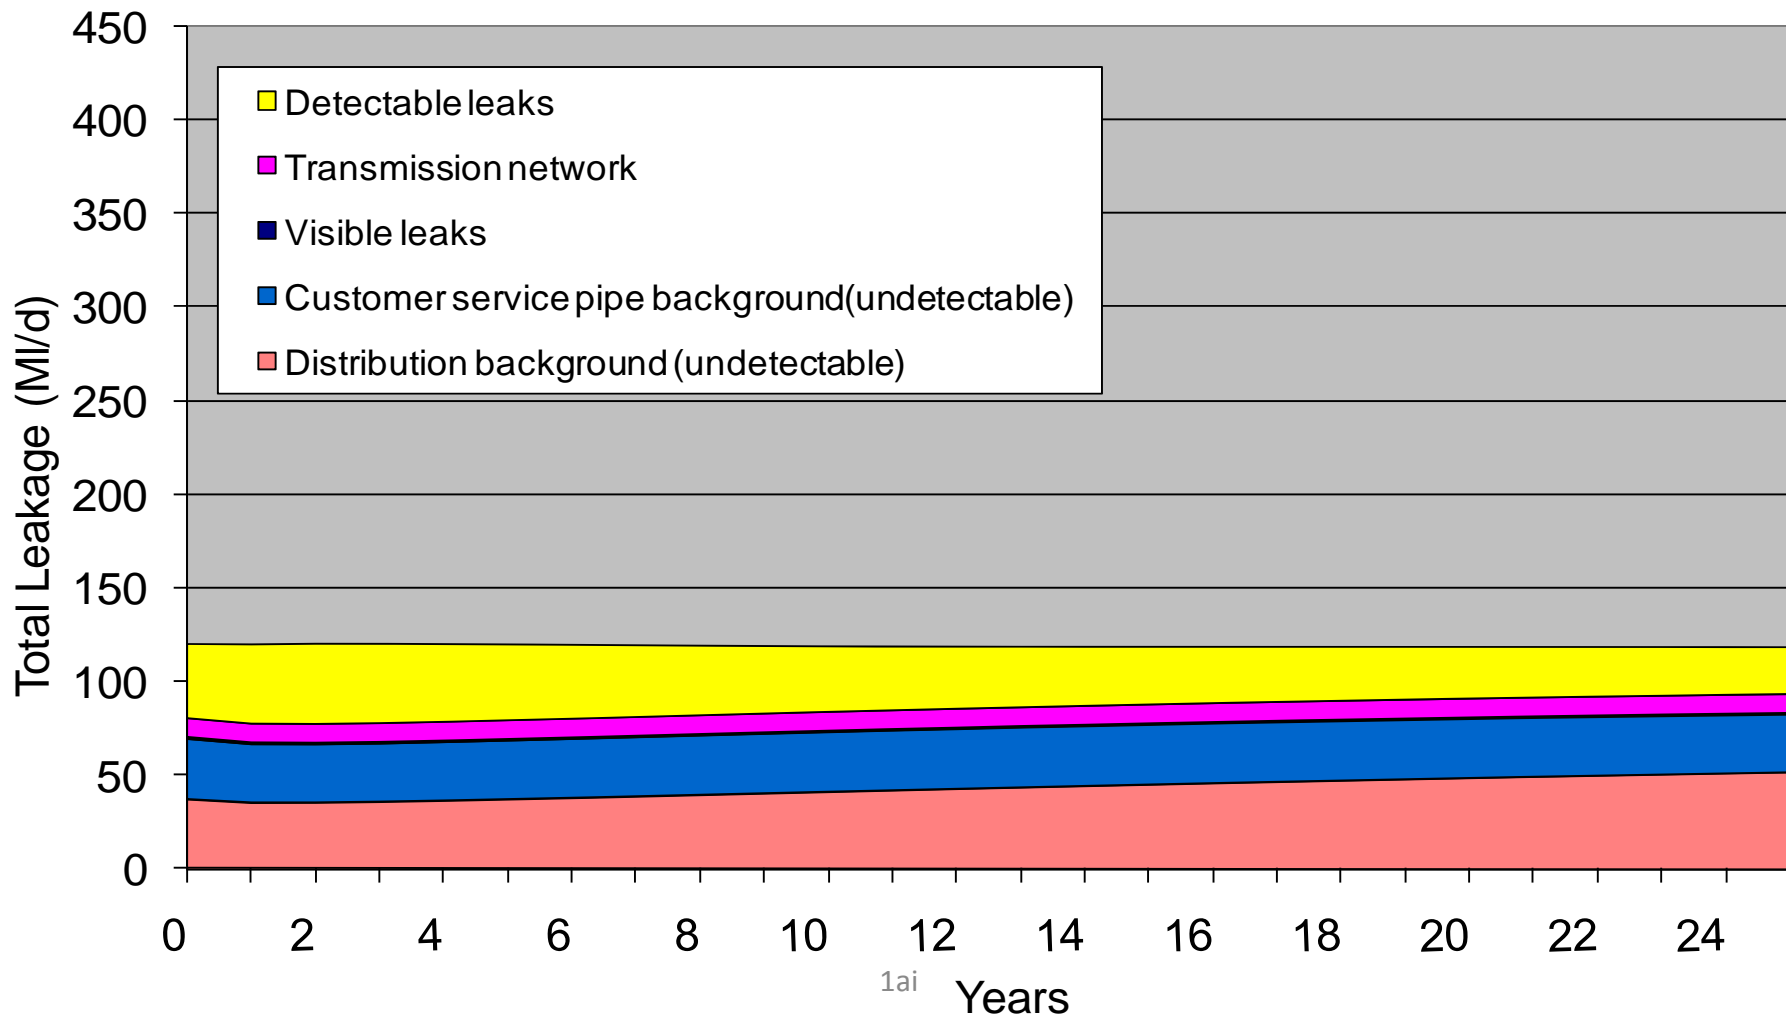

# Outputs: 1% Renewal rate

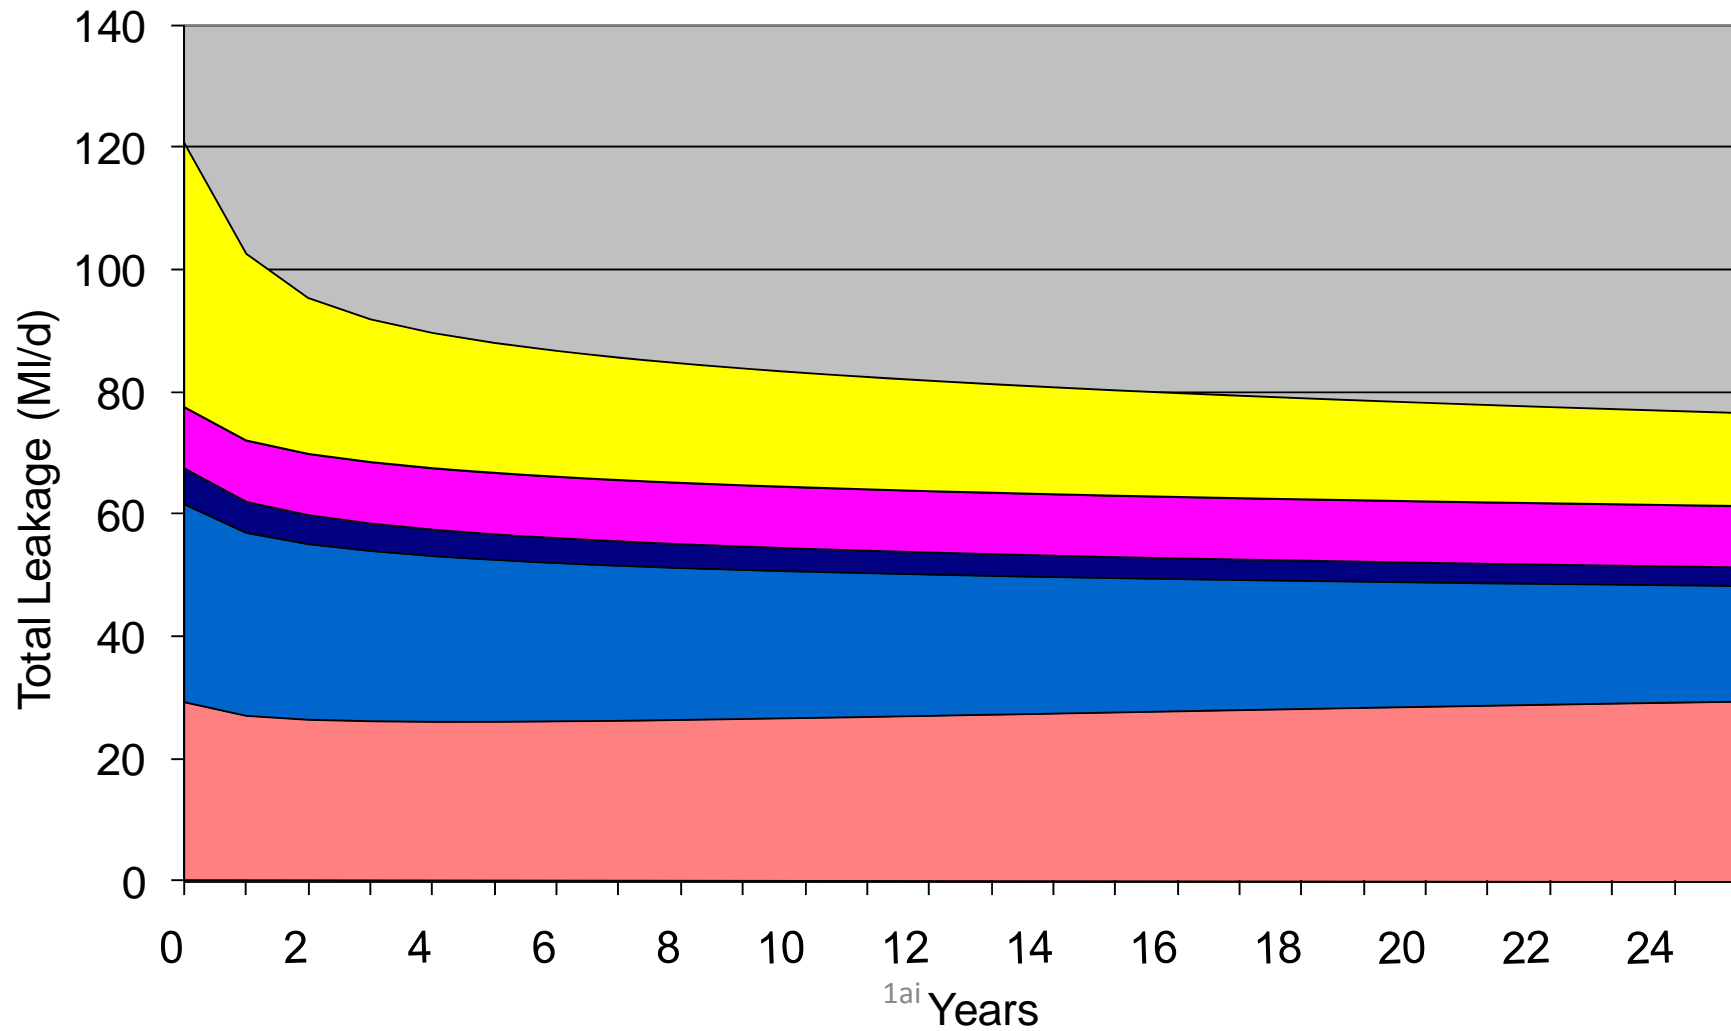

# Outputs: plus ALC

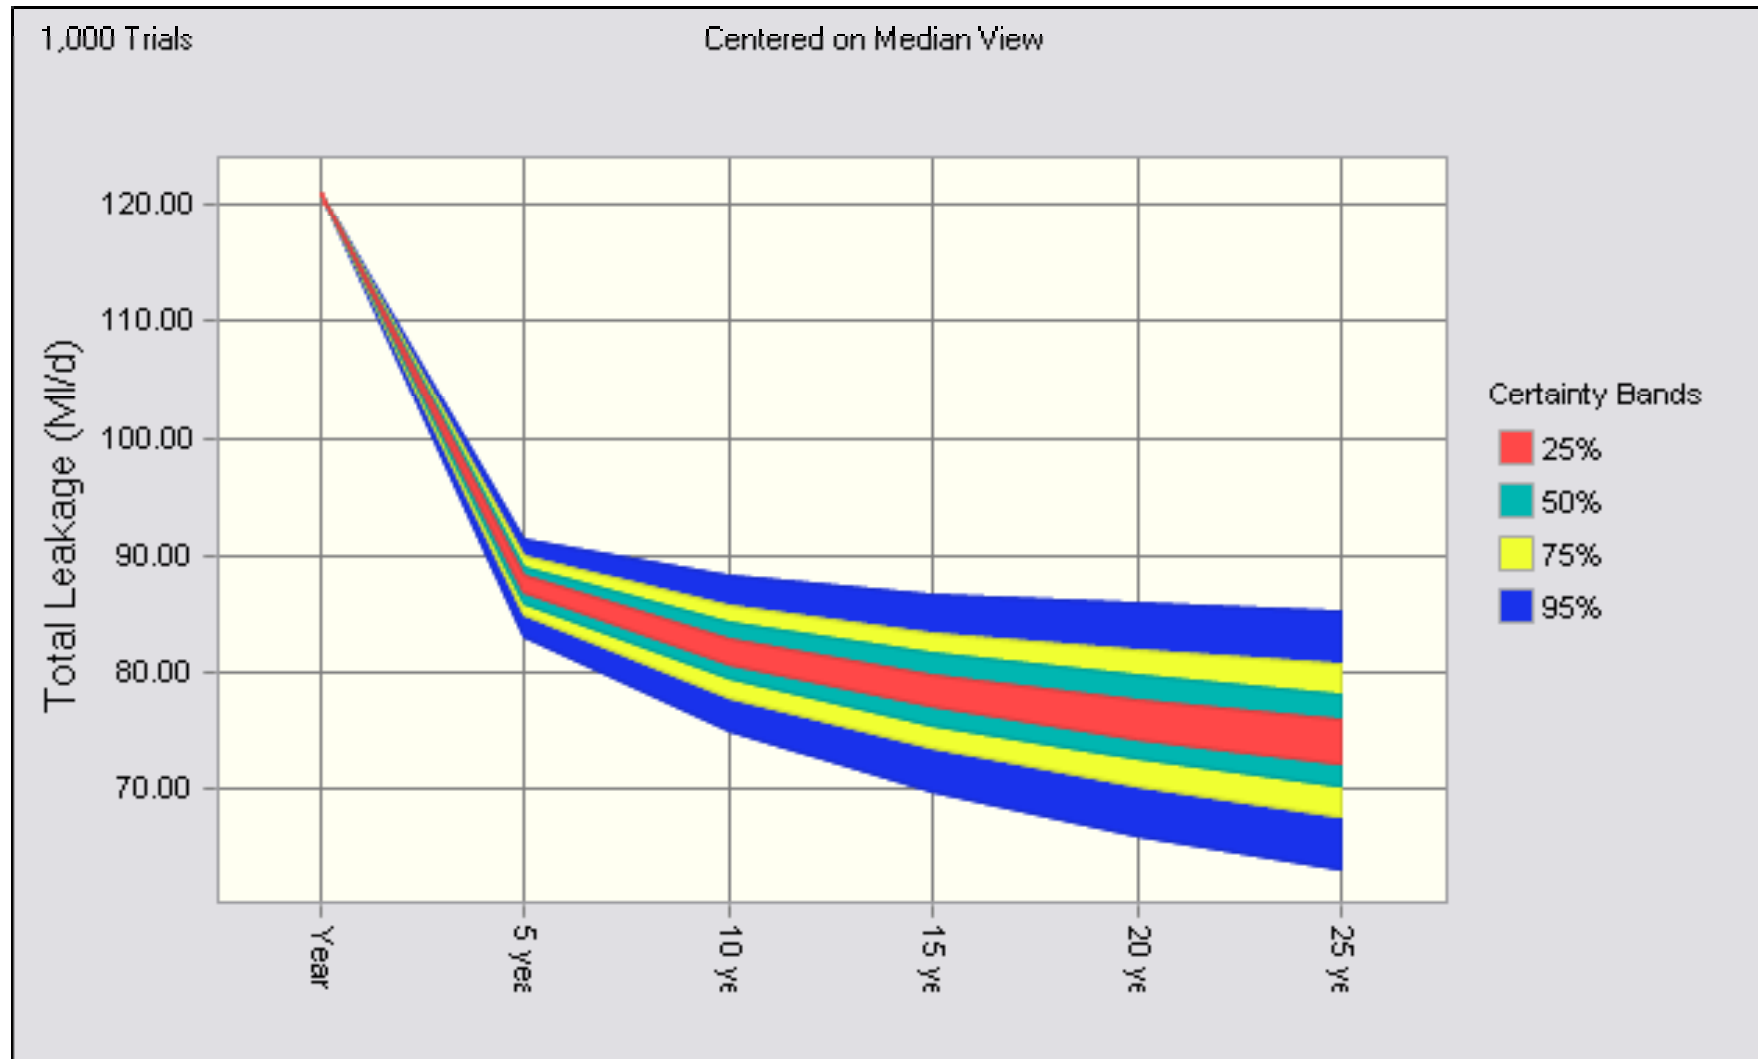

# Output: plus pressure management

# Lowest cost solution: minimum NPC

# Uncertainty in lowest cost leakage forecast

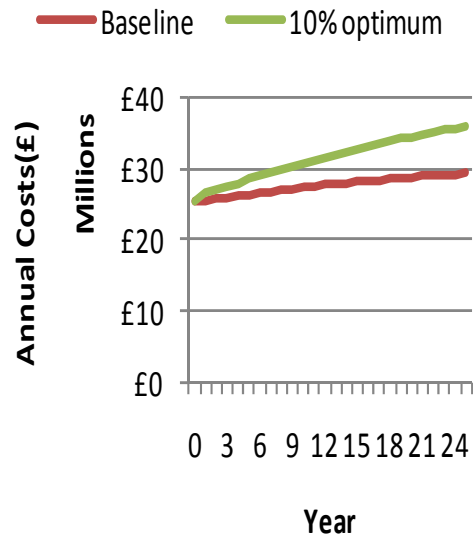

# Sensitivity test optimum yr 25 leakage

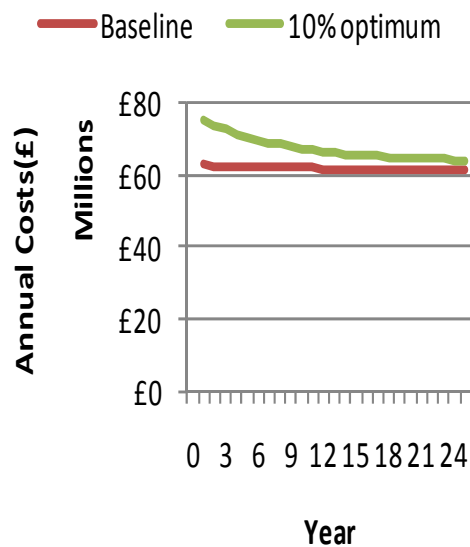

# Outputs: financial projection

## operating costs per annum

## Capital costs per annum

## Total costs per annum

# Contributions to the uncertainty

This approach provides a way to assess:

- the optimum long term leakage level
- The uncertainty in that leakage forecast
- the uncertainty in the expenditure forecast
- the parameters that contribute to the uncertainty

The approach was:

- Developed to understand long term leakage levels in whole countries
- Customisable to individual companies and individual supply zones

Thank you
